

TEST Registration Page Password Field Validation

Test Case ID: Registration-001 **Title:** Verify password field displays validation error when input exceeds 72 character maximum limit.

Feature: Registration / Password Field Validation **Type:** Boundary Analysis, Negative **Priority:** Medium **Status:** Fail

Created By: Demirhan Yalcin **Date:** 18/03/2026 **Environment:** Chrome 122, Windows 10, Desktop

Preconditions

User has access to the registration page and a valid email address that has not been registered before.

Steps

1. Navigate to the registration page.
2. Enter a valid unregistered email address into the email field.
3. Enter a password of exactly 73 characters that meets all other requirements including uppercase, lowercase, number and special character.
4. Click outside the password field or press Tab to trigger validation.
5. Observe the validation message appearing below the password field.

Expected Result

A validation error message appears below the password field stating "Password should be 8-72 characters long." The password is not accepted and the user cannot proceed with registration.

Actual Result

No validation error appeared. The password field accepted the 73 character input without any restriction or error message, contradicting the documented maximum limit of 72 characters.

Notes

Related bug report: Registration-001, Password field accepts input beyond the documented 72 character maximum without validation error. See also TC-Registration-002 for companion boundary test at exactly 72 characters which should pass.
